### Outdoor Photography part 1

Saturday, June 14th 2:00pm - 4:00pm Instructor: Jeannine Lau Wyatt Fertig

http://photographylife.com

#### Today we'll cover:

•Major types of cameras

•lenses

•Manual settings including:

•Image size

•ISO

- •Aperture
- •Shutter Speed

•And tips to make your compositions more interesting with:

- •Lighting
- •Positioning
- •Framing

## Introduction

•Photography skills can far outweigh costly cameras.

•With digital photography the best way to learn is to make mistakes.

•And there is no right or wrong as long as you like the photos you are taking!

## Here at EPL

# The two largest types of cameras (beside smartphones) are the **dslr** and the **point and shoot**

## DSLR vs Point and Shoot

#### DSLR stands for digital single lens reflex

This means that the camera reflects light from a mirror through the lens to the viewfinder, the movement of the reflecting mirror creates the traditional camera noise

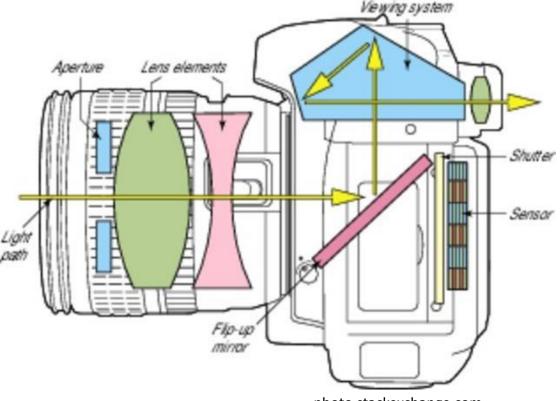

photo.stackexchange.com

DSLR

## **Point and Shoot Cameras** typically have attached lenses, smaller bodies, and less settings

Digital point and shoot cameras typically will not have a viewfinder (which is displayed on the lcd screen)

snapsort.com

## Point and Shoot

#### Prime vs Zoom

**Prime-** Basic lenses which have a fixed focal length, these lenses are usually faster (let more light in on their first aperture setting), also smaller in size

**Zoom-** Lenses which have a adjustable focal length which make them more versatile and require less movement of the photographer

photographylife.com

### Wide-angle, Normal, Telephoto?

Lenses come in varying focal lengths and are used for shooting different subject matter

numbers (18-35mm) and have a wider angle of view

Wide-angle lenses have lower

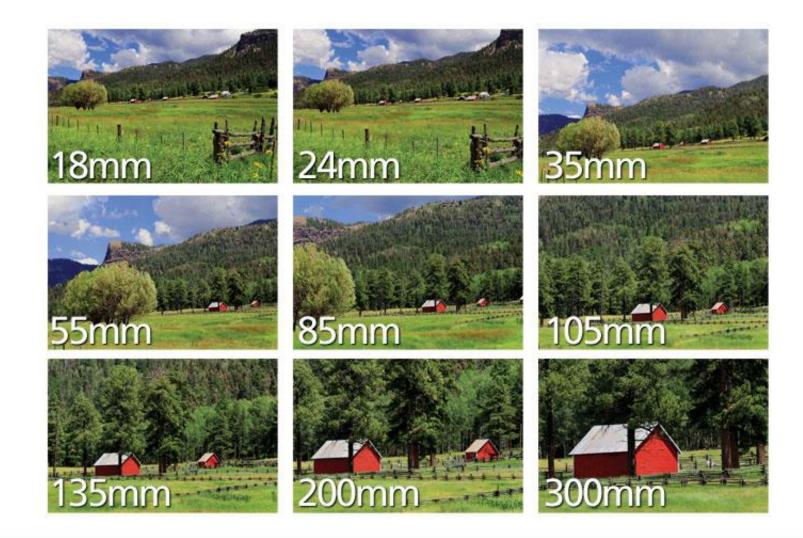

**Normal** is somewhere in between (40-60mm)

**Telephoto** for longer subjects with greater magnification (90mm-and up)

## Lens Types

### Lens Types

People often think they need a more expensive camera, better lenses, or newer equipment but by better understanding the camera's manual settings great *controlled photos* can be taken anywhere with almost any camera

The most important manual settings are:

ISO

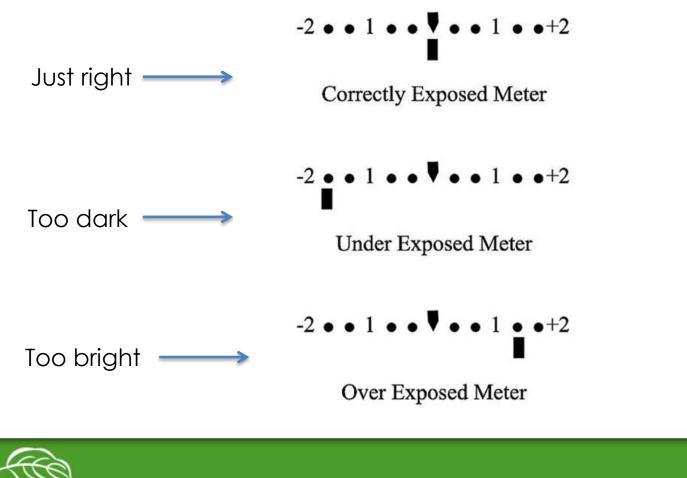

Aperture Shutter Speed

## Manual Settings

Most cameras have an internal light meter which tells whether the exposure is too dark, too bright or just right!

: 1 1

**ISO** is film's technical term to describe the film (when we still had film) or the sensors sensitivity to light. In the past you would pick a film by it's ISO number before shooting also called the film's speed.

Film with a higher ISO number is more sensitive to light but grainer.

Film with a lower ISO number is less sensitive to light and clearer.

And the same goes for digital sensors –which are described as noisy

ISO

Aperture controls the iris of the camera acting like a gateway, letting more or less light in. Lower numbers allow more light than higher ones. Aperture is measured in **F-Stops**.

### Aperture

The final component is **Shutter Speed** which determines how long the exposure is made. This is the time the sensor is exposed to light.

Quick moving objects require a faster shutter speed (less time) to capture subjects without motion blur.

Slower shutter speeds allow for more light.

## Shutter Speed

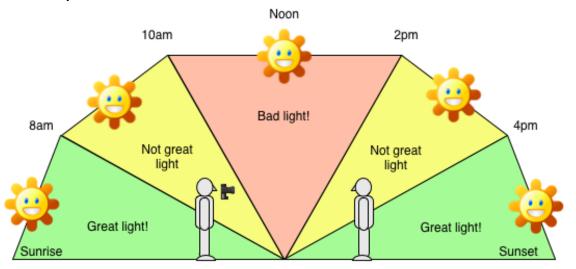

# Shutter Speed

Outdoor lighting can be tricky since the sun and other conditions are constantly changing. Be mindful of your conditions:

Is the light soft (e.g. overcast) or harsh (e.g. sunny)?Where is your light coming from?

•What is the temperature of your light? Warm sunrise, blue light at dusk, or neutral midday?

# Lighting

### **Consider:**

•Where is your light coming from?

•Angle of the sun

#### •Using Shadows

- •Illuminate texture
- •Give dimension and contrast

#### •Soft vs. Hard light

•Soft, non-directional light is the most flattering for portraits

•Hard light: highlight detail and produce strongest colors - best for landscape and architecture

#### •Time and Place

•Sunrise/Sunset creates dramatic lighting

•Subject Matter and Framing

•People or Places

Direction: The light source is positioned behind you Good for: Rich colours, blue skies, showing every detail, eliminating shadows, trouble-free exposures Bad for: Texture, three-dimensional form, lack of shadows

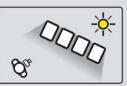

Direction: The light source is to the side of the subject Good for: Texture, three-dimensional form, visible shadows, simple scenes, adding drama Bad for: Obscured detail, complex scenes, clear outlines

www.digitalcameraworld.com

Direction: The light comes from behind your subject Good for: Shape and outline, creating silhouettes, muted colours Bad for: Effort-free exposures, revealing detail, enhancing colour, form and texture

# Lighting

Harsh, direct sunlight Shade & reflected daylight

Sunset highlighting

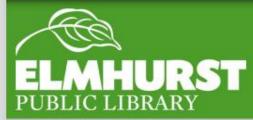

## Lighting

### Flat & overcast

### Dramatic side lighting

# Lighting

### Portraits:

Straight on •Least flattering for most people

Using Angles •Turn the body away from the camera •Position yourself slightly higher than the subject •Lower angles create towering figures

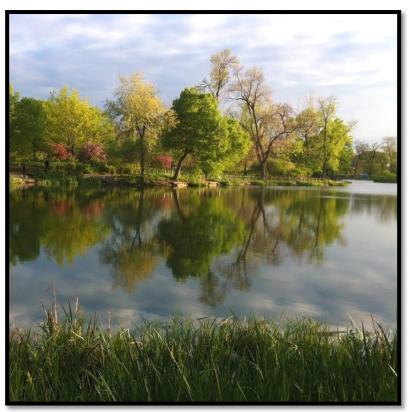

### Landscapes:

•Rule of Thirds

•Try different viewpoints and angles

•Think about your foreground vs. background

### **Tips for Framing:**

•Remember the Rule of Thirds

- •Off-center main subjects
- •Create angled lines

•Zoom in to your subject to create a point of focus or for more detail

# Framing

### **Remember to Consider:**

Your background/foreground
Landscape vs. Portrait Orientation
Use a larger f-stop to create a shallow depth of field to blur busy backgrounds
Where is the sun?

# Positioning

That was a ton of information! The best way to learn, though, is to try adjusting each manual setting and experiment with the results.

We're going to head out into the park now to take pictures feel, **we'll do a quick demo** and then you're free to start shooting and ask any questions as we move along.

## Let's get shooting!

After the class (or after Pt. 2 if you are signed up) email two or three of your best pictures and the class winners work will be displayed on the website and in the building!

### Please Email you pictures to:
